Abstract

SecB, a remarkable chaperone involved in protein export, binds diverse ligands rapidly with high affinity and electron paramagnetic resonance spectroscopy were used to investigate the surface of interaction on SecB in complex with the unfolded precursor form of outer membrane protein OmpA as well as with a transmembrane domain and lacks both the signal peptide and the periplasmic domain. In addition, we study the mature form of galactose-binding protein. We have previously used the same method to study the precursor of galactose-binding protein. We show that for all ligands tested the patterns of contact are the

2. Even though there are no specific sequences that mediate interaction with SecB, the binding to physiologic ligands is constant in the range of 5 nM to 30 nM [5]. This high affinity coupled with low specificity has been attributed to the existence of interaction. Studies with short peptide ligands [19] showed that the SecB tetramer binds one peptide per monomer with a long polypeptide ligand is bound to a tetramer with nanomolar affinity. The interaction of SecB with long stretches of poly

Author Services enables authors to track production and publication of their accepted articles. Additionally, many journals now offer authors free access to their published articles online and the ability to nominate up to 10 colleagues for free access.
